- Decision Tree :
  depth ↓ ▶ Performance ↓, Interpretable ↑
  - depth  $\uparrow$  Performance  $\uparrow$ , Interpretable  $\downarrow$

• No matter how much the depth is increased, the performance on test data does not significantly outperform other models.

- They propose an algorithm that, through **feature learning**, generates a single tree with an appropriate depth for a Decision Tree while achieving good performance.
- Feature learning means that in the decision tree training, instead of X<sub>j</sub> ≤ c, the algorithm contemplates f(X) ≤ c, and learning f during the training process where X = (X<sub>1</sub>,...,X<sub>p</sub>)'.

### Example of feature transformation

(a) A decision tree is relatively complex and generalizes poorly.

(b) A random forest is very complex and generalizes better, but not perfectly.

(c) After rotation, a decision tree is simple and generalizes perfectly.

 Above picture demonstrates that through feature transformation, a single tree can achieve good performance.

- They propose alternating between learning a tree, similar to the CART, and performing feature learning based on gradients.
- For the feature learning, they consider Kernel Density Decision Tree(KDDT) which is differentiable.

#### 1 Introduction

### 2 Fuzzy and Crisp Decision Tree

### **3** Kernel Density Decision Tree(KDDT)

#### 4 Feature learning

#### **6** Fuzzy into Crisp

#### 6 Experiments

Problem of conventional Decision Tree(CART) :

Rule : If  $X \le 3000$ , X is classified as group A else B.

Then, X = 2999 and X = 3001 are classified as different group.

- This causes prediction errors for Decision Trees near the boundaries
- If CART deterministically split data into child node, FDT reflect the possibility of data being split into each child node (e.g., using probabilities)

• Crisp Decision Tree : CART

### 1 Introduction

2 Fuzzy and Crisp Decision Tree

# 3 Kernel Density Decision Tree(KDDT)

- 4 Feature learning
- **6** Fuzzy into Crisp

- KDDT is a model that expresses the likelihood of splitting into child nodes using a kernel to represent probabilities.
- Note that unlike CART, KDDT is the differentiable model.

#### Example

Let  $X \in \mathbb{R}$  be a input vector. Then, we have  $\mathbb{I}(X \in [a_j, b_j]) \rightarrow F(X - a_j) - F(X - b_j)$  where F is cdf of normal.

- **3** Kernel Density Decision Tree(KDDT)

### **4** Feature learning

**6** Fuzzy into Crisp

#### 6 Experiments

- Any differentiable parameterized class of feature transforms can be used.
- example : Linear transformation  $\mathbf{X} \rightarrow A\mathbf{X} + b$
- When training rule in the KDDT, feature learning is conducted based on gradient method for the impurity measure.

- 2 Fuzzy and Crisp Decision Tree
- **3** Kernel Density Decision Tree(KDDT)
- 4 Feature learning
- **5** Fuzzy into Crisp

- In the KDDT paper, they proposed the method for converting fuzzy decision trees to crisp decision trees, and it seems to be employed here.
- However, the details are not elaborated upon, and there is no code available.
- Note that the performance slightly degrades during the converting.

| 351, 34 (34), 2    | -     | -     | 15.5  | 2.2e3 | 5.9e3 | 3.4e2 | 3.9          | 5.5   |

• Even as a single tree, proposed model performs well.

• The above results is from converted crisp proposed model.
